

Video Remote Interpreting (VRI) is a service utilizing video cameras to provide [sign language](#) interpreting services without an interpreter present. A typical VRI setup involves a deaf and hearing user at one location with a camera and television screen, and an interpreter at another location, typically a call center, who also has a camera and television screen. Both cameras offer video and audio connectivity, and the interpreter facilitates communication between the deaf and hearing users who are located together. The hearing person can be heard by the remote interpreter, who interprets into sign language that the deaf person can see on the television monitor. In turn, the deaf person signs to the camera and the interpreter can see what is being said, and then voices it for the hearing person to hear.

The terms Video Remote Interpreting and Video Relay Service should not be confused. The latter was originally called Video Relay Interpreting, but the name was changed and now the terms refer to two separate and distinct services.
